

Abstract of the Disclosure

A method and device for video conferencing between first and second conference locations. Each conference location is provided with a video camera and a video image monitor to carry the image of a video conferee to a remote location. The video cameras are located proximate the video monitors such that each video camera is placed upon an emotionally neutral field of the image of the remotely located conferee and aimed substantially at the eyes of the local conferee facing the conferee's monitor in order to create eye-to-eye contact between conferees while positioning the video camera as to not interfere with said conference.
